

R color cheatsheet

Finding a good color scheme for presenting data can be challenging. This color cheatsheet will help!

R uses hexadecimal to represent colors

Hexadecimal is a base-16 number system used to describe color. Red, green, and blue are each represented by two characters (#rrggbb). Each character has 16 possible symbols: 0,1,2,3,4,5,6,7,8,9,A,B,C,D,E,F:

"00" can be interpreted as 0.0 and "FF" as 1.0
i.e., red = #FF0000, black = #000000, white = #FFFFFF

Two additional characters (with the same scale) can be added to the end to describe transparency (#rrggbbaa)

R has 657 built in color names

To see a list of names:

`colors()`

These colors are displayed on P. 3.

Example:

peachpuff4

R translates various color models to hex, e.g.:

- RGB (red, green, blue): The default intensity scale in R ranges from 0-1; but another commonly used scale is 0-255. This is obtained in R using `maxColorValue=255`. *alpha* is an optional argument for transparency, with the same intensity scale.
`rgb(r, g, b, maxColorValue=255, alpha=255)`
- HSV (hue, saturation, value): values range from 0-1, with optional alpha argument
`hsv(h, s, v, alpha)`
- HCL (hue, chroma, luminance): hue describes the color and ranges from 0-360; 0 = red, 120 = green, blue = 240, etc. Range of chroma and luminance depend on hue and each other
`hcl(h, c, l, alpha)`

A few notes on HSV/HLC

HSV is a better model for how humans perceive color. HCL can be thought of as a perceptually based version of the HSV model....blah blah blah...

Without delving into color theory: color schemes based on HSV/HLC models generally just look good.

R can translate colors to rgb (this is handy for matching colors in other programs)

`col2rgb(c("#FF0000", "blue"))`

R Color Palettes

This is for all of you who don't know anything about color theory, and don't care but want some nice colors on your map or figure....NOW!

TIP: When it comes to selecting a color palette, **DO NOT** try to handpick individual colors! You will waste a lot of time and the result will probably not be all that great. R has some good packages for color palettes. Here are some of the options

Packages: grDevices and colorRamps

grDevices comes with the base installation and colorRamps must be installed. Each palette's function has an argument for the number of colors and transparency (*alpha*):

`heat.colors(4, alpha=1)`
> #FF0000FF" "#FF8000FF" "#FFFF00FF" "#FFFF80FF"

grDevices
palettes
cm.colors
topo.colors
terrain.colors
heat.colors
rainbow
see P. 4 for
options

For the `rainbow` palette you can also select start/end color (red = 0, yellow = 1/6, green = 2/6, cyan = 3/6, blue = 4/6 and magenta = 5/6) and saturation (s) and value (v):
`rainbow(n, s = 1, v = 1, start = 0, end = max(1, n - 1)/n, alpha = 1)`

Package: RcolorBrewer

This function has an argument for the number of colors and the color palette (see P. 4 for options).
`brewer.pal(4, "Set3")`

> "#8DD3C7" "#FFFFB3" "#BEBADA" "#FB8072"

To view colorbrewer palettes in R: `display.brewer.all(5)`

There is also a very nice interactive viewer:

<http://colorbrewer2.org/>

My Recommendation

Package: colorspace

These color palettes are based on HCL and HSV color models. The results can be very aesthetically pleasing. There are some default palettes:

`rainbow_hcl(4)`
"#E495A5" "#ABB065" "#39BEB1" "#ACA4E2"

colorspace
default palettes
diverge_hcl
diverge_hsl
terrain_hcl
sequential_hcl
rainbow_hcl

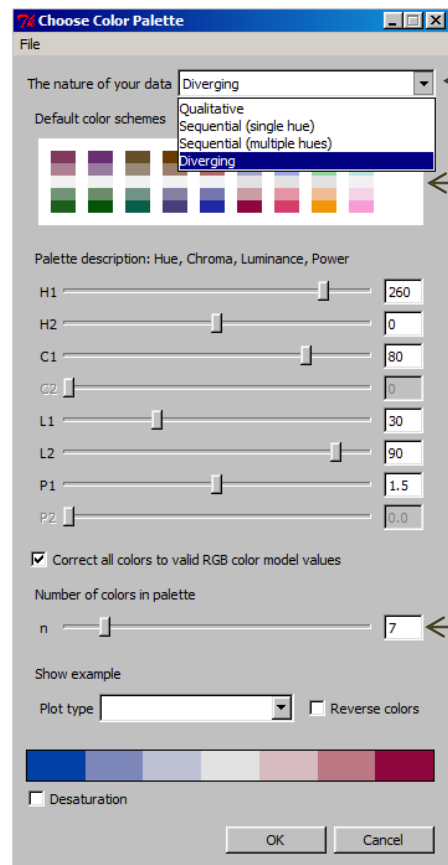

However, all palettes are fully customizable:
`diverge_hcl(7, h = c(246, 40), c = 96, l = c(65, 90))`
Choosing the values *would* be daunting. But there are some recommended palettes in the colorspace documentation. There is also an interactive tool that can be used to obtain a customized palette. To start the tool:
`pal <- choose_palette()`

R color cheatsheet

Overview of colorspace palette selector

`library("colorspace")`

`pal <- choose_palette()`

Select the type of color scheme based on the type of data

Default color schemes – can be used “as is” or as a starting point for modification

Interactively select:

- hue: color
- chroma: low chroma = gray
- luminance: high luminance = pastel
- power: how the color changes along a gradient

Select # of colors in palette

- Save palette for future R sessions:
- txt file with hex codes
 - .R file with a function describing how to generate the palette.

`source` can be used to import the function into R; but one complication is that you have to open the .R file and name the function to use it.

Diverging color schemes:
`diverge_hcl(7, h = c(260, 0), c = 100, l = c(28, 90), power = 1.5)`

Sequential color schemes:
`sequential_hcl(n, h, c = c(), l = c(), power)`

Qualitative color schemes:
`rainbow_hcl(n, c, l, start, end)` (for qualitative schemes; start/ end refer to the H1/H2 hue values)

Display color scheme with different plot types

When “OK” is selected, the color palette will be saved in the R session. To return 7 hex color codes from the selected palette:

`pal <- choose_palette()`
`pal(7)`

[NOTE: These values are not saved if you don’t save the session]

How to use hex codes to define color using the plot function

Discrete variables

Option 1

If you don’t need to control which colors are associated with each level of a variable:

`plot(Sepal.Length ~ Sepal.Width, col=rainbow_hcl(3)[c(Species)], data=iris, pch=16)`

`legend("topleft", pch=16, col=rainbow_hcl(3), legend=unique(iris$Species))`

Option 2

If you want to control which colors are associated with the levels of a variable, I find it easiest to create a variable in the data:

`iris$color <- factor(iris$Species, levels=c("virginica", "versicolor", "setosa"), labels=rainbow_hcl(3))`

`plot(Sepal.Length ~ Sepal.Width, col=as.character(color), pch=16, data=iris)`

Continuous variables

Option 1

Break into categories and assign colors:
`iris2 <- subset(iris, Species=="setosa")`

`color <- cut(iris2$Petal.Length, breaks=c(0,1.3,1.5,2), labels=sequential_hcl(3))`

Or, break by quantiles (be sure to include 0 & 1):
`color <- cut(iris2$Petal.Length, breaks=quantile(iris$Petal.Length, c(0, 0.25, 0.5, 0.75, 1)), labels=sequential_hcl(3))`

`plot(Sepal.Width ~ Sepal.Length, pch=16, col=color, data=iris2)`

Option 2

Fully continuous gradient:

`data <- data.frame("a"=runif(10000), "b"=runif(10000))`

`color=diverge_hcl(length(data$a))[rank(data$a)]`
`plot(a~b, col=color, pch=16, data=data)`

For ggplot2, I think the most flexible color scales are:

`scale_colour_manual`
`scale_colour_gradient`

for discrete and continuous variables, respectively

grDevices::colors
